### Support Vector Machines

Mathematical concept from area of machine learning.

- Used for:
  - classification
  - (regression analysis)
- Supervised learning method
  - Uses training data set
- Binary classifier
  - · Classifies a set of data points into two classes

<ロト <四ト < 回ト < 回 > < 回

# Classification

### Definitions

#### $\bullet\,$ Data samples with D attributes are represented by D-dimensional vectors x.

- Usually  $x \in \mathbb{R}^D$
- C is a finite set of classes.
- Function  $h: \mathbb{R}^D \to C$  assigns a class to every possible data sample x.
  - h is unknown, we want to find its approximation based on some training data.

#### Classification problem

Given a training data set  $\{(\mathbf{x}_1, c_1), ..., (\mathbf{x}_N, c_N)\}$ , where  $c_i \in C$  and  $c_i = h(x_i)$  for  $i \in \{1, ..., N\}$ , produce a function  $\hat{h}$  which approximates h as close as possible.

#### Binary classification

In the case of SVM, there are two classes,  $C = \{1, -1\}$ .

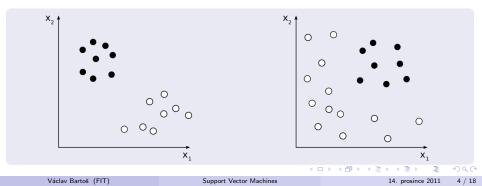

### Linearity

Basic SVM is a linear classifier – data must be linearly separable.

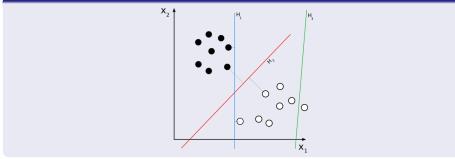

• There is some hyperplane (line for D = 2) separating the two classes.

SVM method finds such hyperplane and use it to classify new data points.

• A class for every new point is assigned according to the side of the hyperplane it lays on.

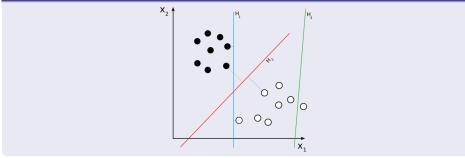

・ロト ・回ト ・ヨト ・

#### Maximum-margin hyperplane

The aim of SVM is to find the maximum-margin hyperplane, i.e. a hyperplane which has the greatest distance to the nearest points from both classes.

A D > A P > A B > A

## Hyperplane

Set of points  $\mathbf{x}$  satisfying:

$$\mathbf{x} \cdot \mathbf{w} - b = 0$$

where:

**w** is hyperplane's normal vector  $\frac{b}{\|\mathbf{w}\|}$  is distance of hyperplane from origin.

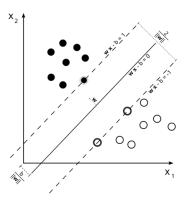

### Margin

Defined by two parallel hyperplanes:

$$\mathbf{x} \cdot \mathbf{w} - b = 1$$
$$\mathbf{x} \cdot \mathbf{w} - b = -1$$

### Support vectors

Points closest to hyperplane – support vectors

A D > A B > A B >

## Margin width maximization

Width of margin is  $\frac{2}{\|\mathbf{w}\|}$  and we want to maximize it. maximize  $\frac{2}{\|\mathbf{w}\|} \equiv \text{minimize } \|\mathbf{w}\| \equiv \text{minimize } \frac{1}{2} \|\mathbf{w}\|^2$ 

Constraints to prevent data points from falling into the margin:

$$\mathbf{x}_i \cdot \mathbf{w} - b \ge 1$$
 for  $x_i$  from the first class  $(c_i = 1)$   
 $\mathbf{x}_i \cdot \mathbf{w} - b \le -1$  for  $x_i$  from the second class  $(c_i = -1)$ .

This can be simplified to:

$$c_i(\mathbf{x}_i \cdot \mathbf{w} - b) \ge 1 \quad \forall i \in \{1, ..., N\}$$

<ロ> (四) (四) (三) (三) (三) (三)

### Optimization problem

Minimize (in  $\mathbf{w}$  and b)

$$\frac{1}{2} \|\mathbf{w}\|^2$$

such that

$$c_i(\mathbf{x}_i \cdot \mathbf{w} - b) \ge 1 \quad \forall i \in \{1, ..., N\}$$

・ロト ・回ト ・ヨト ・ヨト

### Optimization problem

Minimize (in  $\mathbf{w}$  and b)

$$\frac{1}{2} \|\mathbf{w}\|^2$$

such that

$$c_i(\mathbf{x}_i \cdot \mathbf{w} - b) \ge 1 \quad \forall i \in \{1, ..., N\}$$

### Primal form

Using Lagrange multipliers  $\alpha$ , we get (minimize  $L_P$ ):

$$L_P = \frac{1}{2} \|\mathbf{w}\|^2 - \sum_{i=1}^N \alpha_i c_i (\mathbf{x_i} \cdot \mathbf{w_i} - b) + \sum_{i=1}^N \alpha_i$$

#### Dual form

We can also derive a dual form (maximize  $L_D$ ):

$$L_D = \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j c_i c_j \mathbf{x}_i \cdot \mathbf{x}_j$$
$$= \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \alpha^T \mathbf{H} \alpha$$

where  $H = \{h_{ij}\}_{i,j=1}^N$  and  $h_{ij} = c_i c_j \mathbf{x_i} \cdot \mathbf{x_j}$ subject to:

$$\alpha_i \ge 0 \quad \forall_i, \quad \sum_{i=1}^N \alpha_i c_i = 0$$

This can be solved by standard quadratic programming techniques and programs.

#### Classification of new data point

Once we have found the maximum-margin hyperplane (given by  $\mathbf{w}$  and b), we can define classifier as:

$$\hat{h}(\mathbf{x}) = sqn(\mathbf{w} \cdot \mathbf{x} - b)$$

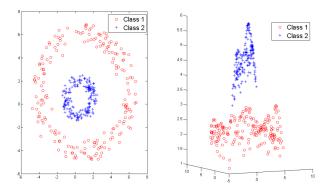

(We simply look on which side of the hyperplane the new point is.)

## Nonlinear classification

### Nonlinear classification

If data are not linearly separable, it's possible to find some mapping  $\varphi : \mathbb{R}^D \to \mathbb{R}^{D'}, \ D' \ge D$ , which transforms data into a higher dimensionality space in which they are linearly separable.

- The second sec

In fact, such transformation is not needed to be computed explicitly.

Dual form of maximization problem in transformed space:

$$L_D(\alpha) = \sum_{i=1}^N \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \varphi(\mathbf{x_i}) \cdot \varphi(\mathbf{x_j})$$

Label the dot product of transformed vectors as a function  $\boldsymbol{k}$ 

$$k(\mathbf{x_i}, \mathbf{x_j}) = \varphi(\mathbf{x_i}) \cdot \varphi(\mathbf{x_j})$$

So we get

$$L_D(\alpha) = \sum_{i=1}^N \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j k(\mathbf{x_i}, \mathbf{x_j})$$

# Nonlinear classification

### Kernel trick

We can use any (nonlinear) kernel function as k to get a nonlinear classifier. We don't need to know transforation  $\varphi$  explicitly, it's implicitly represented by k.

#### Kernel function examples

Some commonly used kernel functions:

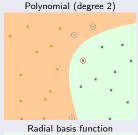

- Gaussian radial basis kernel:  $k(\mathbf{x_i}, \mathbf{x_j}) = \exp(-\gamma \|\mathbf{x_i} \mathbf{x_j}\|^2) \text{ for } \gamma > 0$
- Polynomial kernel:
  - $k(\mathbf{x_i}, \mathbf{x_j}) = (\mathbf{x_i} \cdot \mathbf{x_j} + \alpha)^{\beta}$
- Sigmoidal kernel:  $k(\mathbf{x_i}, \mathbf{x_j}) = \tanh(\alpha \mathbf{x_i} \cdot \mathbf{x_j} - \beta)$

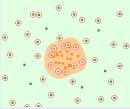

It is also possible to define kernel functions working with more complex data structures (sets, strings, DNA sequences, ...)

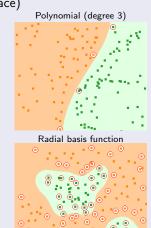

# Nonlinear classification

### Examples of nonlinear SVM

### (hyperplane transformed back to the original space)

#### Multi-class classification

SVM is binary classifier, but it can be used to multi-class classification as well.

- Multi-class classification can be decomposed into several binary classification tasks.
  - One-versus-All, One-versus-One, ...
- There are also some extensions to basic SVM, which allows multi-class classification.
  - Optimization problem becomes much more complex.

• • • • • • • • • • • • •

### Conclusion

- SVM binary linear classifier
  - Finds maximum-margin hyperplane
  - Quadratic programming optimization
- Using kernel trick it can be changed to nonlinear
  - It is usually used in this way.
- Effective especially for large number of dimensions
- Very robust and often used in practice
